TMDB Dataset Schema

1 Movies Dataset

The `movies.parquet` dataset contains one row per movie selected from the TMDB Discover Movie endpoint.

Column	Type
`id`	Integer
`title`	String
`original_title`	String
`release_date`	String / Date
`genre_ids`	List of integers
`original_language`	String
`vote_count`	Integer
`vote_average`	Float
`popularity`	Float

Table 1: Schema of the movies dataset.

2 Credits Dataset

The `credits.parquet` dataset contains the selected cast and crew members associated with each movie.

Only the six actors with the lowest billing order are retained. For the crew, only the roles Director, Producer and Director of Photography are retained.

Column	Type
`movie_id`	Integer
`person_id`	Integer
`person_name`	String
`role`	String
`department`	String / Null
`job`	String / Null
`billing_order`	Integer / Null

Table 2: Schema of the credits dataset.

3 NData Types

The types shown above represent the semantic types of the data obtained from the TMDB API.

In Pandas, some columns appear with different technical types. For example, `genre_ids` appear as `object` because each cell contains a list so the technicla types are printed on the notebook.

The `billing_order` column appear as `float64` because crew members do not have a billing order and therefore contain missing values.

Similarly, `release_date` is initially returned by the API as a string. It is converted to a Pandas datetime type.
